Significant Marine Site Expert Panel

Rob Davidson has been involved in marine biology for over 30 years. Rob holds a Master of Science with First Class Honours from the University of Canterbury, 1987 and has presented 18 conference papers and published 12 papers in internationally peer reviewed scientific journals. He has worked for MAF and the Department of Conservation and since 1994 is the director of an independent science consultancy. During his time at DOC, he coordinated or was involved in many large scale ecological surveys of coastal areas throughout Nelson and Marlborough. Rob compiled this information into the Department's Coastal Resources Inventory which was later reproduced as reports for the Councils' coastal plans. He has implemented monitoring programmes spanning up to 25 years, relating to Cook Strait ferry impacts, marine farm recovery and marine reserve monitoring. As a consultant, Rob has provided scientific information for over 850 resource consent applications and impact assessments. His company has also coordinated a marine ecological database for the Marlborough District Council. Over his working career, he has conducted over 4000 dives throughout the Marlborough area and has an extensive knowledge of the underwater features and values of Marlborough.

Clinton Duffy is a marine scientist employed as a Technical Advisor (Marine) with the Department of Conservation's Marine Ecosystems Team. He holds a M.Sc. (Hons) in Zoology from the University of Canterbury, 1990, and worked as a marine and freshwater technical support officer for the Department's Nelson/Marlborough, East Coast Hawke's Bay and Wanganui Conservancies from 1990-1999, and as a Scientific Officer (marine ecology) in the Science & Research and Marine Conservation Units from 1999-2012. He is a member of the New Zealand Marine Sciences Society, Oceania Chondrichthyan Society and the IUCN Shark Specialist Group — Australia and Oceania. Clinton has authored over 80 scientific publications and reports. His areas of expertise include marine survey and monitoring; biogeography of New Zealand reef fishes, algae and invertebrates; and the conservation biology, taxonomy and behaviour of sharks and rays. He has dived, either in a professional or private capacity, around much of New Zealand's coastline from the Kermadec Islands to Stewart Island, including co-ordination of a dive survey of shallow subtidal habitats of the Marlborough Sounds in 1989-90.

Andrew Baxter has over 35 years' experience in coastal and marine management, specialising in marine ecology including marine mammals. He graduated from the University of Canterbury in 1981 with a BSc with First Class Honours in Zoology. Following two years working for the Taranaki Catchment Commission as a marine biologist, Andrew worked as a fisheries management scientist for MAF Fisheries based in Wellington from 1984 to 1987. He has been employed as a marine ecologist for the Department of Conservation in Nelson since October 1987. Andrew is currently a Technical Advisor in DOC's Marine Species and Threats Team.

Peter Gaze worked for many years with Ecology Division of DSIR, involved with research into the distribution, conservation and economic value of birdlife in New Zealand. This included a study of forest bird ecology, in particular rifleman, kereru and mohua. Peter is a co-author of the first atlas of bird distribution in New Zealand. Various research projects took him to the sub-Antarctic, the Kermadecs, Cook Islands and Tahiti. He then moved to the Department of Conservation where his role was primarily to provide technical advice on fauna conservation work in Nelson and Marlborough. This role enabled him to bring a national perspective to the local matters. Related fields of interest include the impact and control of mammalian predators as well as reptile conservation including leading the department's recovery of tuatara for the last ten years. Both roles have included projects working on the islands and wildlife of the Marlborough Sounds. A plan written for the management of these islands continues to guide the work of the Department. He has a long association with bird research and conservation throughout the country and was for some time the secretary for the Ornithological Society of NZ. Peter has now works for charitable trusts committed to conservation in Abel Tasman National Park and the outer Marlborough Sounds.

Sam du Fresne has over 19 years of experience studying marine mammals, beginning with his master's thesis in 1998. He has conducted several dolphin surveys in New Zealand focussed mainly on Hector's dolphins and has worked in places as diverse as Far East Russia, Hawaii and Western Australia. After graduating with a PhD from the University of Otago in 2005, Sam worked as an independent consultant, specialising in marine mammals. As a consultant, Sam worked closely with DoC, MFish, NIWA, Cawthron, various regional councils and several industry clients, providing expert advice and research services on a range of species and issues. Sam also spent time at SMRU Ltd in St Andrews (Scotland) where he worked as a senior research scientist, focussing mainly on marine mammals and renewable energy projects. Recently, after working for more than three years in Western Australia on mega-projects such as the Gorgon and Wheatstone LNG developments, Sam returned to New Zealand to join the EEZ Compliance team at the Environmental Protection Authority in Wellington.

Shannel Courtney is a Nelson-based plant ecologist with the Department of Conservation, working as a Technical Advisor in the Terrestrial Ecosystems Unit. In 1983 he attained a Master of Science in plant ecology at Canterbury University and before DOC has worked for the NZ Wildlife Service, NZ Department of Lands and Survey and NZ Forest Service on management issues. For much of the earlier part of his career, he has been involved in the assessment of natural areas for ecological significance and has led various ecological surveys of the East Cape, Taranaki, Marlborough and Nelson regions. Relevant publications and co-authorships include Protected Natural Area reports for North Taranaki, Motu and Pukeamaru Ecological Districts and for Molesworth Station, habitat restoration guides for Nelson City and Tasman District, and several publications on the development of a natural character framework for the Marlborough Sounds. For the last 20 years, he has specialised in threatened plant conservation and co-ordinates the recovery of nationally threatened and at-risk species in the Nelson region and Marlborough Sounds. He is currently on the National Threatened Plant Panel and on the committee of the NZ Plant Conservation Network. In 2008 he was awarded the Loder Cup in recognition of his services to plant conservation.

Bruno Brosnan presently works for Te Atiawa o Te Waka-a-Maui as Rohe Manager and was formerly a Coastal Planner at the Marlborough District Council. His qualifications include a Bachelor's of Science in Zoology and Psychology from Massey University, a postgraduate diploma in Marine Science from Otago University, a Master of Science in Marine Science from Otago University investigating recovery and succession of benthic environments after large scale disturbance, a post graduate diploma in Environmental Management from the University of Waikato, a Master of Management Studies from the University of Waikato, and a Master of Planning from Massey University. Bruno is also a qualified diver instructor.

1.0 Summary

Davidson *et al.* (2011) described a total of 129 significant marine sites in Marlborough. In 2015, the Marlborough District Council (MDC) and Department of Conservation (DOC) embarked on an ongoing survey and monitoring programme aimed at updating and improving the significant site database. The programme also aimed to collect new data for repeat monitoring of selected significant sites. This programme was guided by a detailed range of survey protocols including techniques suited for rapid reconnaissance (i.e. qualitative descriptions) and techniques suitable for monitoring (i.e. quantitative and certain qualitative data) (Davidson *et al.*, 2014). Site selection was guided by:

- Sites identified as having limited or old biological information (Davidson et al., 2011).
- Sites where additional information was needed (Davidson et al., 2014).
- Recommended sites suitable for monitoring (Davidson et al., 2014).
- New potential sites based on new information received since 2011.

Two follow-up summer surveys have been undertaken to date. The first was conducted in summer 2014/2015 and targeted 21 sites and sub-sites in the eastern Marlborough Sounds (Davidson and Richards, 2015). The second survey was conducted in the summer of 2015-2016 and targeted 15 sites and sub-sites in the Croisilles Harbour and D'Urville Island areas (Davidson and Richards, 2016). Reports and raw data from these summer surveys were lodged with the MDC. The authors also provided comment on site boundary alterations and recommendations based on new data.

The present report outlines the Significant Marine Site Expert Panel review of sites surveyed during the third survey programme conducted in Croisilles Harbour, D'Urville Island, and outer Sounds areas in the summer of 2017 (Davidson *et al.*, 2017a). The Panel also reviewed sites suggested from a survey of Tory Channel funded by New Zealand King Salmon Ltd. The Expert Panel assessed sites using the seven criteria originally developed by Davidson *et al.* (2011) and modified by the Expert Panel in 2015, 2016 (see Davidson *et. al.*, 2015; 2016) and during the present review. The updated criteria are presented in Appendix 1 of the present report.

The present report also assesses site sensitivity to a range of anthropogenic threats including physical disturbance.

Overall, the Expert Panel accepted the boundary modifications proposed by Davidson *et al.* (2017a) and Tory Channel sites suggested by Davidson *et al.* (2017b). Two other new sites and one new sub-site were also accepted by the review group. The Expert Panel recommended that one site proposed by Davidson *et al.*, (2017a) be reassessed in the future once more information was available.

2.0 Background

In 2011, a report outlining Marlborough's known ecologically significant marine sites was produced for MDC and DOC (Davidson *et al.* 2011). The assembled group of expert authors ("Expert Panel") developed a set of criteria to assess the relative biological importance of each site. Sites that received a medium or high score were termed "significant". A total of 129 significant sites were recognized and described during that process.

The authors stated that their assessment of significance was based on existing data or information; however, they noted that many sites had limited or old information. Some marine sites had not been surveyed or the information available was incomplete, patchy or potentially not reflective of the current state of the sites. The authors stated that more investigation was required to better assess the status of many significant sites.

The authors also stated that many of the sites not assessed as "significant" had the potential to be ranked higher in the future as more information became available. Further, they recognized that the quality of some existing significant sites may decline over time due to natural or human related events or activities. The authors therefore acknowledged that their assessments would require updating on a regular basis.

Davidson *et al.* (2013) produced a protocol for receiving information for new candidate sites and for reassessing existing ecologically significant marine sites. The goal of that protocol was to establish consistency and to ensure a rigorous and consistent process for site identification, data collection and assessment. The aims of that report were to establish:

- The level of information required for new candidate sites.
- The process for assessing new sites and reassessing existing sites.
- A protocol for record keeping, selection of experts and publication of updated reports.

Davidson *et al.* (2014) provided guidance on the collection, storage and publication of biophysical data from potential new significant sites as well as existing sites. The biological investigation process was separated into three main elements:

- Survey of new sites;
- Collection of additional information from existing significant sites or sites that previously were not ranked as being ecologically significant; and
- Status monitoring of existing significant sites (i.e. site health checks).

Davidson et al. (2014) also detailed a range of candidate sites for survey and monitoring. The authors also provided comment on survey protocols including techniques suited for rapid

reconnaissance (i.e. qualitative descriptions) and techniques suitable for monitoring (i.e. combinations of both qualitative and quantitative data collection).

Follow-up surveys were undertaken in the summers of 2014-2015 (21 sites and sub-sites in eastern Marlborough Sounds), 2015-2016, (15 sites and sub-sites in the Croisilles Harbour and D'Urville Island areas), and 2016-2017 (15 sites and sub-sites predominately from the Croisilles Harbour around to Waitui Bay, outer Marlborough Sounds). Davidson and Richards (2015, 2016) and Davidson et al. (2017a) summarised the new biological data; raw data were provided to MDC for storage. The authors also commented on site boundary alterations and recommended any necessary changes to the assessments of significance. On the previous two and the present occasion, the Expert Panel was reconvened to reassess the new information and make recommendations.

The present report presents the Expert Panel review of the 2016-2017 survey season reported in Davidson *et al.* (2017a) and a survey of Tory Channel funded by New Zealand King Salmon Ltd. The Panel also comments on anthropogenic threats and vulnerability of significant sites.

3.0 The assessment process

3.1 Data collation

All data collected by Davidson *et al.* (2017a) were compiled and made available to the expert panel during the present review.

Davidson *et al.* (2017a) suggested one site (Titi Island) be split into 3 sub-sites, while one site (Rangitoto Islands) be split into four sub-sites. These authors defined sub-sites as having comparable habitats and communities, but each sub-site was physically separate. One new sub-site was added to an existing set of three sub-sites at Hunia (Port Gore). In total, Davidson *et al.* (2017a) described 15 sites and sub-sites in their study.

Davidson et al. (2017b) identified three major habitat types each split into sub-sites (Table 1).

- (1) Sixteen sub-sites supported combinations of bryozoans, sponges, ascidians, hydroids and variety of other invertebrate species (78.2 ha). Sites west of Te Rua Bay were comparable to the north and south-western sites described by Davidson and Richards (2015) (i.e. Sites 5.1 to 5.4). Sites east of Te Rua were comparable to Site 5.8 (Davidson and Richards, 2015).
- (2) The authors also suggested 14 sub-sites (12.2 ha) supporting subtidal eelgrass beds.
- (3) Two sub-sites supporting subtidal beds of drift macroalgae on soft substratum were also recommended as significant sites (41.9 ha).

Information collected during field work included: high definition and low-resolution drop camera photographs, hand held still photography, hand held video, remote video, sonar images, and observations (note: all raw data are held by MDC). Information relating to each original site surveyed by Davidson *et al.* (2011) was also compiled and made available including: site description, site boundaries, ecological assessment, and any data previously compiled or known for the site or sub-site.

3.2 Expert Panel

For the present review, most of the Expert Panel involved in the Davidson *et al.*, (2011) report and subsequent review in 2015 and 2016 were reconvened, apart from Sam du Fresne (marine mammals) and Shannel Courtney (plants). Peter Gaze reviewed new data for a new king shag site located in Tawhitinui Reach prior to the group assessment; this assessment was also reviewed by the other panel members to ensure consistency. Sam du Fresne and Shannel Courtney were not involved in the present reassessment meeting as no new or resurveyed marine mammal or plant sites were under scrutiny; however, all experts reviewed and commented on the present report and are therefore included as authors.

4.0 Wording of the assessment criteria

During the previous Expert Panel reviews (Davidson *et al.* 2015; 2016), the panel members recognized a need to clarify some of the original assessment criteria used by Davidson *et al.* (2011) to avoid any possible misinterpretation. The Expert Panel applied the revised criteria during the reassessment of surveyed sites in 2014-2015 and 2015-2016 survey years.

During the present review, some further minor revisions to the criteria were proposed and adopted (see Appendix 1 for revised criteria). During this process, the Expert Panel took great care not to create inconsistency between the sites assessed in Davidson *et al.* (2011) and the subsequent reassessments. It is recognised, however, that some 2011 significant sites will require future reassessment using the revised criteria to ensure a consistent approach is adopted. A more comprehensive review of the criteria to incorporate recent advancements in assessment criteria in New Zealand is also being considered.

5.0 Review of survey sites (2016-2017)

The Expert Panel assessed all sites and sub-sites based on the information and proposed changes presented in Davidson *et al.* (2017a) (Table 1) and recommended the following.

- Accept the new significant site at Tawhitinui Bay (king shag colony).
- Accept the new significant site at Bonne Point, eastern D'Urville Island (rhodolith bed).

- Accept the new sub-site at Hunia coast, Port Gore (tubeworms).
- <u>Reject</u> the proposed new site at Titi Island offshore rock. The review panel considered there was insufficient evidence to support the new site and recommended further field work.
- Accept boundary adjustments for the remaining significant sites.
- Accept new biogenic sub-sites in Tory Channel.
- Accept new subtidal eelgrass beds in Tory Channel
- Accept subtidal macroalgae beds, however, more survey work is required to confirm these features are permanent.

The agreed boundary refinements lead to both increases (588.1 ha) and decreases (-458.9 ha) to the size of individual significant sites with an overall increase of 129.2 ha between 2011 and 2017 (Table 2).

Table 1: Summary of suggested significant sub-sites from the Davidson *et al.* (2017b) survey.

Site	Community type	Area (ha)	Benthos type
5.4e Katoa Point	Bryozoan, sponge, ascidian, hydroid	3.31	Granules, shell, sand, silt boulder, cobble, bedrock
5.4f Te Weka Bay	Bryozoan, sponge, ascidian, hydroid	4.5	Granules, shell, sand, silt boulder, cobble, bedrock
5.4g Moioio Island	Bryozoan, sponge, ascidian, hydroid	4.19	Granules, shell, sand, silt boulder, cobble, bedrock
5.4h Kaihinui Point	Bryozoan, sponge, ascidian, hydroid	2.95	Granules, shell, sand, silt boulder, cobble, bedrock
5.4i Papatea Point	Bryozoan, sponge, ascidian, hydroid	7.57	Granules, shell, sand, silt boulder, cobble, bedrock
5.4j Tio Point	Bryozoan, sponge, ascidian, hydroid	6.28	Granules, shell, sand, silt boulder, cobble, bedrock
5.4k Motukina Point	Bryozoan, sponge, ascidian, hydroid	7.97	Granules, shell, sand, silt boulder, cobble, bedrock
5.4l Te Rua (west)	Bryozoan, sponge, ascidian, hydroid	2.13	Granules, shell, sand, silt boulder, cobble, bedrock
5.4m Tapapaweke Point	Bryozoan, sponge, ascidian, hydroid	2.16	Granules, shell, sand, silt boulder, cobble, bedrock
5.4n Puhe Point	Bryozoan, sponge, ascidian, hydroid	4.66	Granules, shell, sand, silt boulder, cobble, bedrock
5.4m Te Rua (east)	Bryozoan, sponge, ascidian, hydroid	19.75	Granules, shell, sand, silt boulder, cobble, bedrock
5.8g Tipi Bay (west)	Bryozoan, sponge, ascidian, hydroid	2.36	Granules, shell, sand, silt boulder, cobble, bedrock
5.8h Tipi Bay (east 1)	Bryozoan, sponge, ascidian, hydroid	1.47	Granules, shell, sand, silt boulder, cobble, bedrock
5.8i Tipi Bay (east 2)	Bryozoan, sponge, ascidian, hydroid	3.61	Granules, shell, sand, silt boulder, cobble, bedrock
5.8kThoms Bay (west)	Bryozoan, sponge, ascidian, hydroid	3.16	Granules, shell, sand, silt boulder, cobble, bedrock
5.8l Thoms Bay (east)	Bryozoan, sponge, ascidian, hydroid	2.11	Granules, shell, sand, silt boulder, cobble, bedrock
5.10a Motukina (east)	Subtidal eelgrass	0.61	Sand, silt
5.10b Te Rua (east 1)	Subtidal eelgrass	0.09	Sand, silt
5.10c Te Rua (east 2)	Subtidal eelgrass	0.19	Sand, silt
5.10d Te Rua (east 3)	Subtidal eelgrass	0.27	Sand, silt
5.10e Te Rua (east 4)	Subtidal eelgrass	0.36	Sand, silt
5.10f Te Rua (east 5)	Subtidal eelgrass	0.79	Sand, silt
5.10g Te Rua (east 6)	Subtidal eelgrass	0.82	Sand, silt
5.10h Tipi Bay (west)	Subtidal eelgrass	0.14	Sand, silt
5.10i Tipi Bay (east 1)	Subtidal eelgrass	0.1	Sand, silt
5.10j Tipi Bay (east 2)	Subtidal eelgrass	0.13	Sand, silt
5.10k Tipi Bay (east 3)	Subtidal eelgrass	0.08	Sand, silt
5.10l Thoms Bay (west)	Subtidal eelgrass	3.78	Sand, silt
5.10m Thoms Bay (east 1)	Subtidal eelgrass	4.23	Sand, silt
5.10n Thoms Bay (east 2)	Subtidal eelgrass	0.63	Sand, silt
5.11a Ngaruru Bay (east)	Subtidal drift macroalgae	39.61	Silt
5.11b Ngaruru Bay (west)	Subtidal drift macroalgae	2.32	Silt
Totals		132.33	

Table 2. Summary of significant site assessment by expert review panel.

Site	Biological features	Review panel recommendations	Original data	New area (ha)	Change (ha)	Reason/s for change
Site 1.2 Croisilles Harbour Entrance (habitat & lancelet)	Physical structure, lancelets	Accept new data	368.5	492	123.50	Additional quantitative data
Site 2.6 Rangitoto Islands (A, B, C, D) (biogenic community)	Biogenic structures	Adjust boundary to encompass values	429.8	168.5	-261.30	Improved detail of survey

7. Catchment	L(low)	NA
Comments	Previously the area was either investigated Davidson and Richards (2016)	Sub-site 2.6b supports a rare biogenic habitat and is therefore ranked as
	and Davidson and Brown (1994). The present survey intensifies the level	"high" in representativeness. This area in 2.6b is regarded as best bryozoan
	of data collected. Sonar and depth soundings of much of the deep areas of	dominated habitat on mud/shell substratum in Marlborough. Recovery
	the original significant area showed a low likelihood of biogenic habitats.	times for bryozoans growing on mud are likely to be extremely long.
	The survey concentrated in areas where sonar and previous studies have	
	detected biogenic habitats. The reduction in the area between 2011 and	
	the present study is likely due to more accurate survey methods. Data	
	from Davidson and Brown (1994) suggested biogenic habitats were	
	located on the eastern side of Wakaterepapanui Island. The present	
	survey focussed on this area.	
Recommendations	Adjust boundaries to fit the biogenic habitats. Significant Sites 2.5a-c be	Provide high level of protection for all sites.
	deleted and included in sites 2.5 a-d. Protect habitats from all physical	
	disturbance.

Site 2.27 Titi Island (biogenic communities)

Site Registration Detail (original)	Existing and present survey information	Expert panel assessment
Site number	2.27	2.27 (a-c)
Site name	Titi Island (subtidal)	Titi Island (subtidal)
Site description	Titi island is located approximately 4.6 km west of Forsyth island. Titi	Titi island is located approximately 4.6 km west of Forsyth island. Titi island
	island covers 24ha and has a circumference of approximately 3.3 km, and	is 24 ha and has a circumference of approximately 3.3 km. The island is
	is approximately 1.2 km long and 300m wide (Davidson et al., 2011).	approximately 1.2 km long and 300m wide (Davidson et al., 2011). The sea
	Davidson et al. (2011) stated "The soft sediment seafloor along the	around the island comprises a variety of substrata and habitats that are
	northern shoreline of Titi island supports a variety of biogenic habitat-	often wave or current influenced.
	forming species including horse mussels, hydroids, sponges and	
	bryozoans. Horse mussels, hydroids and sponges are relatively common at	
	the north-western end of the island in water 20-30m deep. Large colonies	
	of the Separation Point coral live below 30m along the northern side of	
	the island."	
Ecological description of attributes	The site supports biogenic structures dominated by variable proportions	The site supports biogenic structures dominated by bryozoans, sponges,
	of bryozoans, sponges, ascidians and a variety of other biogenic habitat	ascidians and a variety of other biogenic habitat forming species. Sub-sites
	forming species. Functions provided by biogenic habitats are diverse, and	a, b and c are distinct, each chracterised by a range of habitats, communities
	can include the elevation of biodiversity, bentho-pelagic coupling,	and environmental regimes giving this site, as a whole, a high diversity
	sediment baffling, protection from erosion, nutrient recycling, the	score.
	provision of shelter and food for a wide range of other organisms, and	
	even the creation of geological features over longer time scales	
	(Bradstock and Gordon 1983; Turner et al., 1999; Carbines and Cole, 2009;	
	Wood et al., 2012; Morrison et al., 2014). Morrison et al. (2014) stated, a	
	range of biogenic habitats also directly underpin fisheries production for a	
	range of species, through: 1) the provision of shelter from predation, 2)	
	the provision of associated prey species, and in some cases, 3) the	
	provision of surfaces for reproductive purposes e.g. the laying of	
	elasmobranch egg cases; as well as, 4) indirectly in the case of primary	
	producers through trophic pathways.

Site 2.30 Waitui Bay (biogenic communities)

Site Registration Detail (original)	Existing and present survey information	Expert panel assessment
Site number	2.30	2.3
Site name	Waitui Bay	Waitui Bay
Site description	Waitui Bay is remote and large north-facing bay located west of Cape	Waitui Bay is remote and large north-facing bay located west of Cape
Site description		
	Lambert and opens directly into Cook Strait. Waitui Bay has a coastline of	Lambert and opens directly into Cook Strait. Waitui Bay has a coastline of
	approximately 13.28 km, a sea area of 1310 ha and the mouth of Waitui	approximately 13.28 km, a sea area of 1310 ha and the mouth of Waitui Bay
	Bay is approximately 6.2 km wide (Davidson et al., 2011). Davidson et al.	is approximately 6.2 km wide (Davidson et al., 2011). The original site
	(2011) reported that based on a study by Cameron Hay (DSIR), a large area	described in Davidson et al. (2011) was based on work done on a horse
	of central Waitui Bay supported horse mussels and associated encrusting	mussel bed located in the central bay by Cameron Hay (DSIR).
	species. The author stated this bed was one of the two largest horse	masser bear located in the sentral bay by cameron may (bonny).
	_ ·	
	mussel beds in the biogeographic area.	
Ecological description of attributes	The site supports biogenic structures dominated by variable proportions	The new significant site supports biogenic structures dominated by variable
	of bryozoans, sponges, ascidians and a variety of other biogenic habitat	proportions of bryozoans, sponges, ascidians and a variety of other biogenic
	forming species. Functions provided by biogenic habitats are diverse, and	habitat forming species including low numbers of horse mussels. The site
	can include the elevation of biodiversity, bentho-pelagic coupling,	appears to be impacted by historic physical damage.
		appears to be impacted by instone physical damage.
	sediment baffling, protection from erosion, nutrient recycling, the	
	provision of shelter and food for a wide range of other organisms, and	
	even the creation of geological features over longer time scales	
	(Bradstock and Gordon 1983; Turner et al., 1999; Carbines and Cole, 2009;	
	Wood et al., 2012; Morrison et al., 2014). Morrison et al. (2014) stated, a	
	range of biogenic habitats also directly underpin fisheries production for a	
	range of species, through: 1) the provision of shelter from predation, 2)	
	the provision of associated prey species, and in some cases, 3) the	
	provision of surfaces for reproductive purposes e.g. the laying of	
	elasmobranch egg cases; as well as, 4) indirectly in the case of primary	
	producers through trophic pathways.

	and covers an area of sea of approximately 79.5 ha. The mouth of	length of approximately 2.97 km and covers an area of sea of approximately
	Tawhitinui Bay is approximately 1900 m wide. This site was briefly visited	79.5 ha.
	on two occasions during the present study and photos were collected. A	
	previous aerial survey counted 43 birds and 16 active nests (Schuckard et	
	al., 2015).	
Ecological description of attributes	The New Zealand king shag is endemic to New Zealand, only occurring in	One of only two mainland breeding colonies in Marlborough.
	the Marlborough Sounds. Subfossil bone deposits indicate two regional	
	haplogroups, from the Cook Strait region and northern North Island.	
	However, king shags have been confined to the outer Marlborough	
	Sounds for at least 240 years (NZ birds online). King shags are restricted to	
	the outer Marlborough Sounds, from the west coast of D'Urville Island	
	east to where Queen Charlotte Sound and Cook Strait meet. About 85% of	
	all existing birds are located at five colonies: Rahuinui Island, Duffers	
	Reef, Trio Islands, Sentinel Rock and White Rocks. The shags feed up to 25	
	km in a predominantly southwest direction from the main colonies,	
	mainly in waters up to 50 m deep (but diving in deeper waters has been	
	recorded). The foraging area of king shag is estimated to be 1300 km2.	
	Away from the Marlborough Sounds, there are records of single king shags	
	from Wellington Harbour (July 2002), and Kaikoura (October 2011). In 2015	
	and 2016 seven individual king shags, mostly 1st and 2nd year birds, were	
	recorded from Abel Tasman National Park. The International Union for	
	Conservation of Nature threat classification is "Vulnerable to extinction"	
	and under the New Zealand Threat Classification System the species has	
	the status "Nationally Endangered". This means the species is considered	
	threatened with extinction due to its low population numbers, the	
	limited area of occupancy (usually considered to be the nesting habitat of	
	seabirds) and limited extent of occurrence (foraging range at sea). The	
	total population of King Shags is likely to be less than 1000 birds and more	
	than 800. The most recent full population census in February 2015	
	identified 839 birds (Schuckard et al., 2015).

Site 5.4 Tory channel west (biogenic structures)

Site Registration Detail (original)	Existing and present survey information	Expert panel assessment
Site number	5.4e-n	5.4 e-n
	Tory channel bryozoan, sponge, ascidian and hydroid community	Tory Channel west (bryozoan, sponge, ascidian and hydroid
Site name Site description	There are seven existing current swept significant sites located along the	community)
Site description	north-west and south-west edges of Tory Channel (Davidson and	
	Richards, 2015). The new sites described here are comparable to sites 5.1,	
	5.2, 5.3, and 5.4a, 5.4b, 5.4c and 5.4d (Davidson and Richards, 2015).	
	Communities are often, but not always associated with rocky structures.	
Ecological importance	Bryozoans, sponges and hydroids create biogenic habitats that provide	
	three dimensional structures on the benthos. These habitats are utilised by a wide variety of species including juvenile fish.	
	by a wide variety of species including juvernie fish.	
Human Impacts		
Damage and or impacts noted	No impact on benthos noted during survey, but trawling occurs along the	Some dredging for kina may occur in Tory Channel. No trawling is

SIGNIFICANT SITE SUMMARY	Existing and present survey information	Expert panel assessment
Original area of significant site (ha)	3.63	
	Te Pangu Bay (subtidal)	Katoa Point (3.3 ha). Te Weka Bay (4.4 ha), Tapapaweka Point (2.16
		ha), Moioio Island (4.2 ha), Kaihinu Point (2.95 ha), Papatea Point (7.6 ha), Tio Point (6.3 ha), Motukina point (7.97 ha), Te Rua (west)(2.1
		ha), Te Rua (east)(19.8 ha), Tipi (west)(2.36 ha), Tipi Bay (east1)(1.5
		ha), Tipi Bay (east2)(3.6 ha), Thoms Bay (west)(3.2 ha), Thoms Bay
		(east)(2.1 ha), Puhe Point (4.7 ha). Total = 78 ha.
Recommended area of significant site (ha)	45.72	
Change to original site	Increase	
Change (ha)	42.09	
Percentage change from original area (%)	92.0	
Anthropogenic disturbance	Kina dredging may occur. Three salmon farms are located along the edges	
and the second distance	of the main reach. Several mussel farms are located in adjacent bays to	
	the main reach. Pine plantations are widespread in most catchments of	
	the bays along Tory Channel. The intertidal and shallow subtidal received	
	wakes from ferry passage.	
Vulnerability assessment	Medium to high (bryozoans, sponges and hydroids are vulnerable to	
	physical disturbance). Many remnant habitats are associated with	
	outcropping rock that appears to provide refuge from physical damage.

Site 5.8 Tory Channel east (biogenic structures)

Site Registration Detail (original)	Existing and present survey information	Expert panel assessment	
Site number	5.8g-I	5.8g-l	
	Tory channel hydroid, bryozoan, sponge and ascidian community	Tory Channel east (hydroid, bryozoan, sponge and ascidian	
Site name	,	community)	
Site description	There are six existing significant sub-sites along the current swept north-		
	eastern edges of Tory Channel (Davidson and Richards, 2015). The new		
	sites described here are comparable to sites 5.8a-f (Davidson and		
	Richards, 2015). Communities are often, but not always associated with		
	rocky structures.		
Ecological importance	Bryozoans, sponges and hydroids create biogenic habitats that provide		
	three dimensional structures on the benthos. These habitats are utilised		
	by a wide variety of species including juvenile fish.

Site 5.10 Tory Channel east (subtidal eelgrass beds)

	Existing and present survey information	Expert panel assessment		
Site Registration Detail (original) Site number	Enisting and present survey information	5.10 a-n		
Site name	Outer Tory Channel (subtidal eelgrass)	Tory Channel east (subtidal eelgrass)		
Site description	14 new sub-sites supporting subtidal eelgrass.	,		
Ecological importance	Permanently submerged beds of seagrass (Zosteraceae) in coastal waters			
	are rare in New Zealand, where most seagrass beds are confined to the			
	intertidal zone of estuaries (Schwarz et al., 2006). Subtidal beds are			
	knowns from offshore islands including Slipper Is (Bay of Islands), Cavallis			
	and Great Mercury Island. Seagrasses including eelgrass are among the			
	most productive plants of earth (McRoy and McMillan, 1977; Knox, 1986;			
	Duarte and Chiscano, 1999) a and influence community structure and			
	function through a combination of physical, chemical, and biological			
	mechanisms (Phillips 1984, Thayer et al., 1984). Declining seagrass			
	populations worldwide have been largely due to increases in			
	anthropogenic disturbance (Short and Burdick, 1996) including lowered			
	water quality or clarity, nutrient and sediment loading from runoff and sewage disposal, dredging and filling for navigation, pollution, upland			
	development, and commercial fishing (Fonseca et al., 1984; Short and			
	Burdick, 1996; Short and Wyllie-Echeverria, 1996). At present, no

Site 5.11 Ngaruru Bay subtidal drift algae

Site Registration Detail (original)	Existing and present survey information	Expert panel assessment	
Site number	Zinoting and present saire j mornique.	5.11	
Site name	Ngaruru Bay (subtidal drift macroalgae)	Ngaruru Bay (subtidal drift macroalgae)	
Site description	Two new sub-sites supporting subtidal drift macroalgae.		
Ecological importance	Drift macroalgae is known to be very productive and may provide habitat for a variety of species (Knox, 1986; Norkko et al., 2000). Norkko et al.		
	(2000) stated drifting algae at a site in Finland at times supported very		
	high abundances of invertebrates (up to 1116 individuals/g algal dry		
	weight), surpassing invertebrate densities recorded in seagrass		
	communities. Britton-Simmons et a l. (2012) stated the export of large		
	amounts of detritus derived from nearshore macrophyte production into		
	deep-water habitats likely fuels extensive secondary production in their study area located in offshore aphotic zones. Drift material is an excellent		
	food resource (Wilson et al., 1990) since it tends to have elevated levels		
	of nitrogen (Mann, 1988) and diminished levels of defensive chemicals		
	(Duggins and Eckman, 1997). Drift macroalgae may also provide shelter		
	and enhance dispersal mechanisms for other species (Holmquist, 1994). This resource could therefore be important for driving marine secondary		
	productivity.		
Human Impacts	The second second	<u> </u>	
Damage and or impacts noted	No impacts noted during survey.	Dredging and trawling in this area is unlikely.

SIGNIFICANT SITE SUMMARY	Existing and present survey information	Expert panel assessment	
Original area of significant site (ha) Sites and sub-sites	Tory Channel subtidal drift macroalgae		
Recommended area of significant site (ha)	41.9		
Change to original site			
Change (ha)	0		
Percentage change from original area (%)	0.0		
Anthronogonic disturbance	None observed		
Anthropogenic disturbance Vulnerability assessment	Little is known about anthropogenic threats to drift macroalgal beds on		
Tumerability assessment	soft substratum. It is probable that threats may be indirect and associated		
	with the source of drift macroalgae. There are numerous studies		
	documenting a decline of living macroalgal beds on rocky substrata due		
	factors such as climate change, ecosystem changes (e.g. predation) and		
	environmental variable (e.g. reduced light penetration) (Smale <i>et al.</i> , 2013). MacDiarmid <i>et al.</i> (2012) concluded that kelp forests on sheltered		
	coasts were affected by 39 threats.

6.0 Significant site sensitivity and anthropogenic disturbance

6.1 Anthropogenic impacts

Many of Marlborough's significant marine sites contain biological features considered uncommon and remnants of habitats and communities that were likely once more widespread (Davidson *et al.* 2011; Davidson and Richards 2015; 2016; Handley 2015, 2016). This situation reflects a global trend of declining biogenic habitats (area and quality) with consequential effects on wider ecological values (Thrush *et al.*, 2006a, 2006b; Gray *et al.*, 2006; Lotz *et al.*, 2006; Airoldi *et al.*, 2008; McCauley *et al.*, 2015). For example, in New Zealand, a decline in biogenic habitats has been linked to declining juvenile fish habitats and, therefore, a decline in fish abundance and biomass (see Morrison *et al.* 2014 for review).

The site assessment criteria used by Davidson *et al.* (2011) relied heavily on identifying the best or better sites remaining in each biogeographic area. In certain cases, the biological values represented the last, or best remaining of their kind, based on existing knowledge. Their survival was often due to environmental factors such as topography or substratum that provided some level of natural protection from anthropogenic impacts.

Loss and degradation of marine biological values around New Zealand and internationally has usually been linked to anthropogenic activities (Lauder 1987, Stead 1991, Cranfield *et al.* 1999, Cranfield *et al.* 2003, Morrison *et al.*, 2009; Davidson *et al.*, 2011; Paul 2012; Morrison *et al.*, 2014, 2014a; Handley 2015, 2016). Direct physical disturbance, for example from trawling and dredging, has been assessed as one of the main causes of damage to marine benthic biological values (MacDiarmid *et al.*, 2012; MfE, 2016). It is likely that without protection or strong management, Marlborough's less resilient significant marine sites will continue to be lost or degraded.

Davidson and Richards (2015) highlighted the decline of biological attributes at several significant sites originally identified by Davidson *et al.* (2011), including sites becoming smaller and some being functionally lost. In contrast, Davidson and Richards (2016) did not document loss that could be directly attributed to human activities; rather site boundaries were adjusted based on improved information and data. Both scenarios were reported by Davidson *et al.* (2017).

6.2 Threat assessment process

For each significant site, the Expert Panel assessed anthropogenic threats (Table 3). These were based on:

- (4) The perceived level of anthropogenic disturbance (e.g. dredging recorded).
- (5) Each species, community or habitats vulnerability to anthropogenic impact (e.g. fragile species).
- (6) Significant site vulnerability to anthropogenic impact (e.g. site located on an offshore soft bottom, site located next to rocky reef).

This assessment was based on the panel's collective knowledge of the biophysical characteristics of each significant site (e.g. personal knowledge) and/or from the literature (including bathymetry charts).

Similar approaches have been adopted by Halpern *et al.* (2007) and further adapted for the assessment of New Zealand's marine environment by MacDiarmid *et al.* (2012). Robertson and Stevens (2012) described an ecological vulnerability assessment (originally developed by UNESCO (2000)) for use at estuarine sites in Tasman and Golden Bays. The UNESCO methodology was designed to be used by experts to represent how coastline ecosystems were likely to react to the effects of potential "stressors".

Definitions for the threat categories used in the assessment of threats were:

Anthropogenic disturbance: Known or expected (based on experts' experience) level of impact associated with human-related activities. Disturbance levels range from little or no disturbance (low score) to sites regularly subjected to disturbance (high score). Impacts range from direct physical disturbance to indirect effects, including those from the adjacent catchments.

Sensitivity: Assessment of the sensitivity of habitats, species and/or communities present at a site. Scores ranged from extremely sensitive biological features such as lace corals and brittle tubeworm mounds (high vulnerability score) to relatively robust species or habitats such as coarse substrate/mobile shores and high energy kelp forests (low vulnerability score).

Anthropogenic vulnerability is an assessment of a habitat, species and/or community's vulnerability to human derived damage by nature of location or the level of physical or legal protection. For example, a very shallow community is regarded as having a low vulnerability to damage from dredging and trawling, while a marine reserve has a high level of legal protection from anthropogenic impacts.

Table 3. Selected environmental categories used to assess threat.

Categories	Descriptions, definitions and examples
Anthropogenic disturbance	
Low	Little or no known human associated physical disturbance. Catchment effects low (vegetated).
Moderate	Light equipment and/or anchoring disturbance. Well managed catchment.
High	Subjected to regular or heavy equipment seabed disturbance, and/or catchments modified and poorly managed.
Sensitivity (species, habitat)	
Resilient (low or unlikely)	Algae forest, coarse mobile substrata, reef, boulder bank, high energy shore, short-lived species.
Sensitive (moderate)	Horse mussels, soft tubeworms, shellfish beds, red algae bed.
Very sensitive (high)	Massive bryozoans, sponges, hydroids, burrowing anemone.
Extremely sensitive (very high)	Lace or fragile bryozoan colonies, tubeworm mounds, rhodoliths.
Anthropogenic vulnerability	
Low	Legally or physically protected e.g. in a reserve, on rocky substrata, on a steep slope.
Moderate	Limited or difficult access e.g. close to rocks, shallow, close to shore. Limited or no legal protection.
High	Location easily accessed, no legal protection e.g. offshore soft bottom substratum.

6.3 Assessment summary

Sites 3.1 (Harris Bay) was ranked as both resilient for species and location as well as being subject to a low level of human impact (Table 3). This site is shallow, in a bay considered unsuitable for dredging and trawling. Sites 2.33 (Hunia tubeworms) and 2.5 (Bonne Point rhodoliths) were also ranked as having low levels of disturbance and physical vulnerability due to their location. For example, Bonne Point rhodoliths were protected from dredging and trawling due to the presence of a reef; however, the site is considered vulnerable to anchoring impacts.

Site 1.2 (Croisilles Entrance) was assessed as has having a high level of physical disturbance, but was dominated by a resilient habitat and infauna. In contrast, sites 2.6, 2.10 and 2.30 supported fragile biogenic communities and were assessed as vulnerable to physical damage. Only biogenic communities growing on rock were assessed as having a low level of physical vulnerability (e.g. 2.27 Titi Island).

Site 2.6 (Rangitoto Passage) was subjected to human impacts, but these were considered patchy. Some habitats present at the Rangitoto site remained free of disturbance because of their location on or near rocky reefs, but were regarded having a high species/community sensitivity due to their fragile nature.

Subtidal eelgrass beds in Tory Channel are fragile and vulnerable to physical disturbance from activities such as anchoring or from catchments effects such as sedimentation. Pine forest clearance in adjacent areas for example, would likely lead to smothering.

The Expert Panel recommends that all sites that are regarded as sensitive or vulnerable to anthropogenic disturbance (Table 4) be given a level of protection that ensures their biological values are not further degraded.

7.0 Erratum

The following are errors to the Davidson et al., (2011) report.

Sites	Anthropogenic disturbance	Sensitivity (species, habitat)	Anthropogenic vulnerability	Comments
Site 1.2 Croisilles Harbour Entrance (habitat & lancelet)	High	Resilient	Low	Resilient habitat and species to recreational dredging
Site 2.6 Rangitoto Islands (A, B, C, D) (biogenic community)	Moderate	Extremely sensitive	High	Rare and fragile biogenic community on soft substrata
Site 2.10 Trio Islands (west) (biogenic community)	Moderate to high	Extremely sensitive	High	Fragile biogenic community on soft substrata
Site 2.27 Titi Island (A, B, C)(biogenic community)	Moderate	Extremely sensitive	Low	Fragile biogenic restricted to or near rock
Site 2.30 Waitui Bay (biogenic community)	Moderate to high	Extremely sensitive	High	Biogenic community on soft substrata
Site 2.33 Hunia Coast (tubeworms)	Low	Sensitive	Low	Community in very shallow water
Site 3.1 Harris Bay (algae)	Low	Resilient	Low	Community in shallow water
Site 2.5 Bonne Point (rhodolith bed)	Low	Extremely sensitive	Low	Protected by reef, wilnerable to anchoring
Site 3.23 Tawhitinui Bay (king shag)	Moderate	Extremely sensitive	High	Area used by recreational fishers
Site 5.4 e-m Tory Channel western biogenic habitats	Moderate	Extremely sensitive	Moderate	Fragile biogenic restricted to or near rock, fringes vulnerable
Site 5.8 g-l Tory Channel eastern biogenic habitats	Moderate	Extremely sensitive	Moderate	Fragile biogenic restricted to or near rock, fringes vulnerable
Site 5.10 a-n Tory Channel subtidal eelgrass	Low	Extremely sensitive	High	Very vulnerable physical disturbance, moorings and anchoring
Site 5.11 a-b Ngaruru Bay subtidal macraoalgae beds	Low	Resilient	Low	Likely resilient to physical disturbance

Appendix 1. Assessment criteria (2017)

The following section presents the updated assessment criteria used to evaluate the ecological significance in the present review report. The ranking for each criterion are: H = High (which can be thought of as outstanding), M = Medium (which is still highly significant) and L = Low (which is more representative or typical of ecosystems that pre-dated human disturbance). Criteria scores collectively contribute to the overall site ranking and indicate the reason/s for a sites significance. Site that do not achieve "H" or "M" are not ranked as reaching the planning threshold of being an ecologically significant site in the present report, however, such sites may possess a variety of biological attributes considered important for other reasons or have insufficient data to enable ranking.

1. Representativeness

The site is significant if it contains biological features (habitat, species, community) that represent a good example within the biogeographic area.

High: The site contains the best example of its type known from the biogeographic area.

Medium: The site contains one of the better examples, but not the best, of its type known from the biogeographic area.

Low: The site contains an example, but not one of the better or best, of its type known from the biogeographic area.

2 Rarity

The site is significant if it contains flora and fauna listed as nationally threatened nationally endangered, nationally vulnerable, or in serious decline. The site is also considered significant if it supports flora and fauna that are sparse, locally endemic, or at an extreme in their national distribution. The site is also significant if it supports a habitat or habitats or community assemblages that are rare nationally, regionally or within the biogeographic area.

High: The site contains a nationally important species, habitat or community; or the site contains several species, habitats, communities that are threatened within the biogeographic area.

Medium: The site contains one or a few species, habitats or communities that are threatened but not nationally, or contains rare or uncommon species, habitats or communities within the biogeographic area. **Low:** The site is not known to contain flora, fauna or communities that are threatened, rare or uncommon in the biogeographic area, region or nationally.

3 Diversity

The site is significant if it contains a range of species and habitat types notable for their complexity (i.e. diversity of species, habitat, community).

High: The site contains a high diversity of species, habitats or communities.

Medium: The site contains a moderate diversity of species, habitats or communities.

Low: The site contains a low diversity of species, habitats or communities.

4 Distinctiveness

The site is significant if it contains ecological features (e.g. species, habitats, communities) that are outstanding or unique nationally, in the region, or in the biogeographic area.

High: The site contains any ecological feature that is unique nationally, in the region, or in the biogeographic area, or it contains several features that are outstanding regionally or in the biogeographic area.

Medium: The site contains any ecological feature that is notable or unusual but not outstanding or unique nationally, in the region or in the biogeographic area.

Low: The site contains no known ecological features that are outstanding or unique nationally, in the region or in the biogeographic area (i.e. ecological features are typical rather than distinctive).

5 Size

The site is significant if it is moderate to large relative or other habitats or communities of its type in the biogeographic area.

High: The site is large relative to other habitats or communities of its type in the biogeographic area.

Medium: The site is moderate size relative to other habitats or communities of its type in the biogeographic area.

Low: The site is small relative to other habitats or communities of its type in the biogeographic area.

6 Connectivity

The site is significant if it is adjacent to, or close to other significant marine, freshwater or terrestrial areas or the site is sufficiently close to other sites of its kind to enable biological interchange (e.g. larval transport, settlement of juveniles).

High: The site is near or well connected to a large significant site or several other significant sites.

Medium: The site is near other significant sites, but only partially connected to them or at an appreciable distance.

Low: The site is isolated from other significant sites.

7 Adjacent catchment modifications

Catchments that drain large tracts of land can lead to high sediment loading into adjacent marine areas. A site is significant if the adjacent catchment is >400 ha and clad in relatively mature native vegetative cover resulting in a long term stable environment with markedly reduced sediment and contaminant run-off compared to developed or modified catchments.

High: The site is dominated by a stable and relatively mature native vegetated catchment (>400 ha) that is legally protected.

Medium: The site is dominated by a stable and relatively mature native vegetated catchment (>400 ha) with partial or no legal protection.

Low: The site is surrounded by a catchment (>400 ha) that is farmed, highly modified or has limited, relatively mature, vegetative cover.

Not applicable: The site is little influenced by catchment effects (e.g. offshore site, current swept site).
